A. Additional Figures and Tables

Figure A1: Scatterplots of vote shares against soybean harvests, 2007-2015

Panel A: Legislative vote

Panel B: Presidential vote

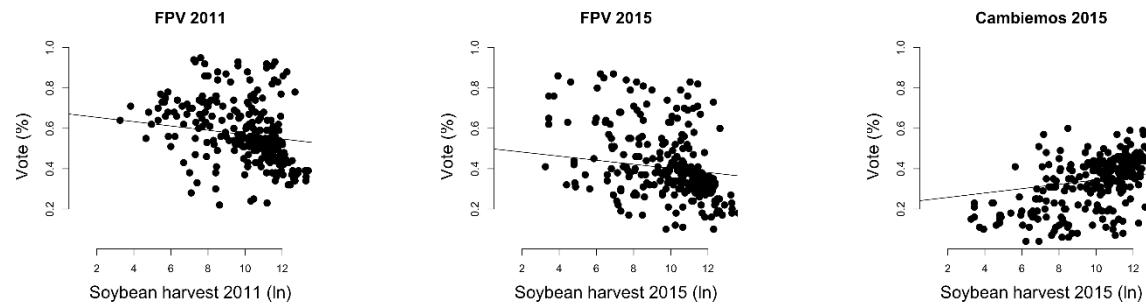

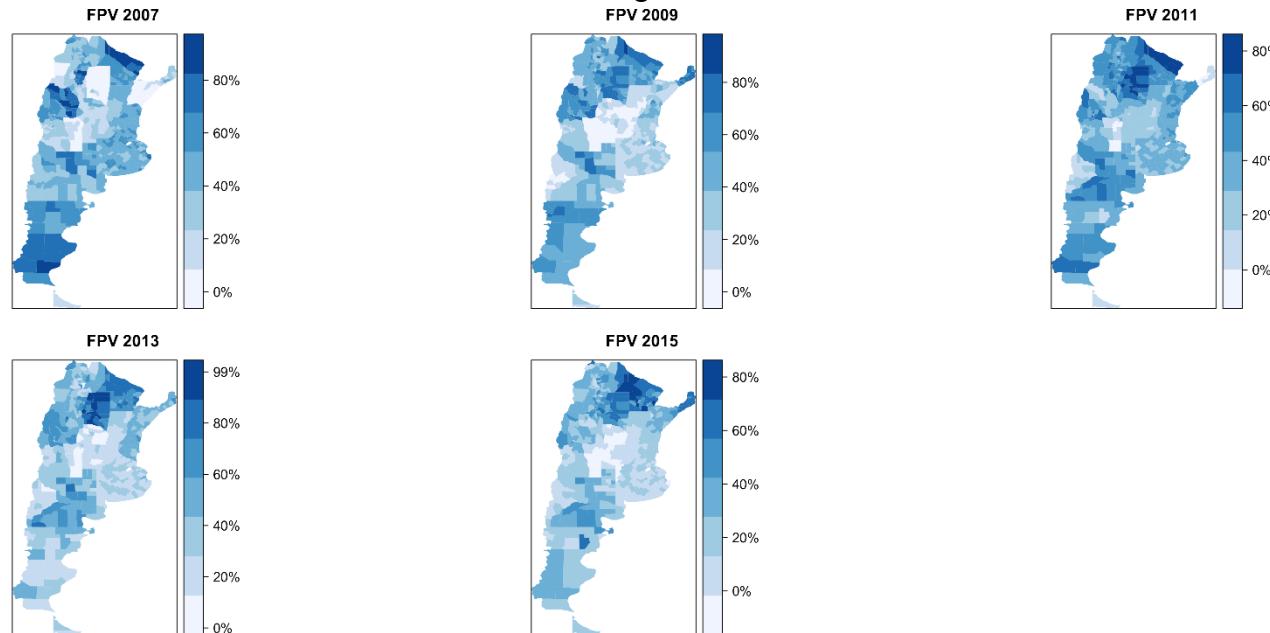

Figure A2: Spatial distribution of the vote, 2007-2015

Panel A: Legislative vote

Panel B: Presidential vote

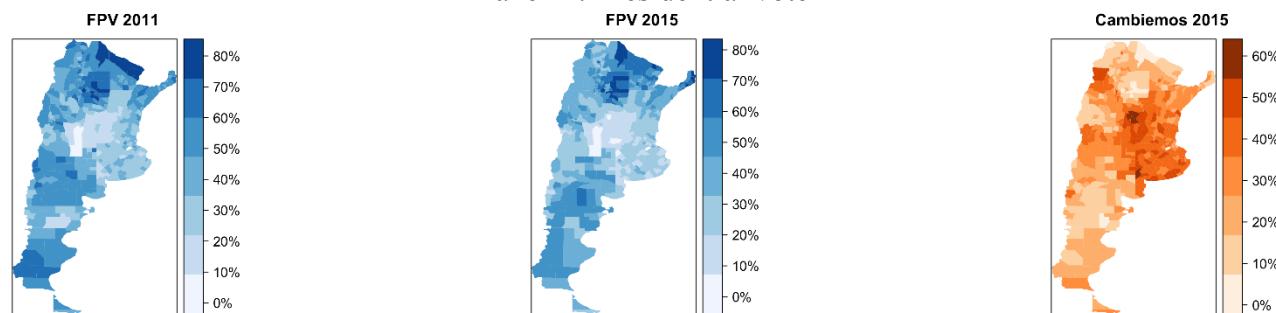

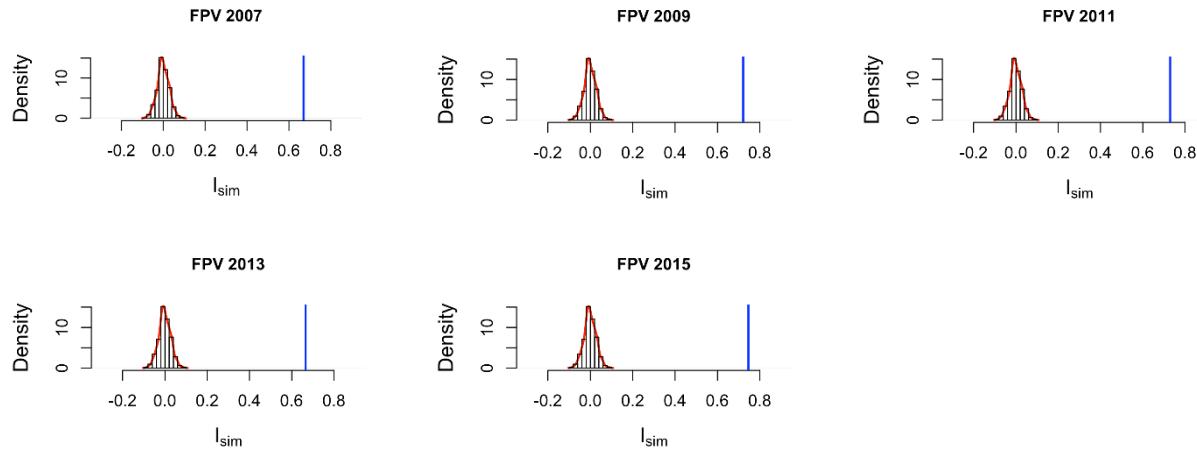

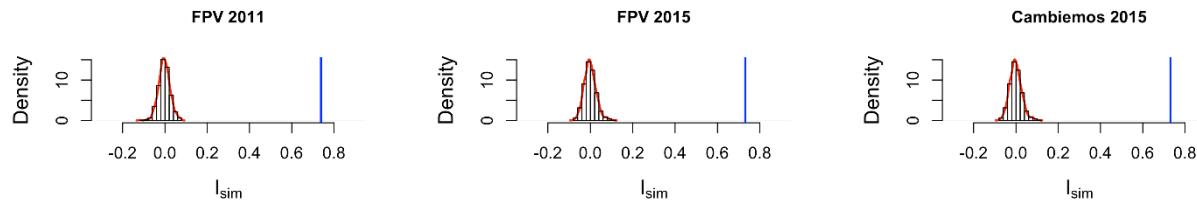

Figure A3: Moran's I permutation tests

Panel A: Legislative vote

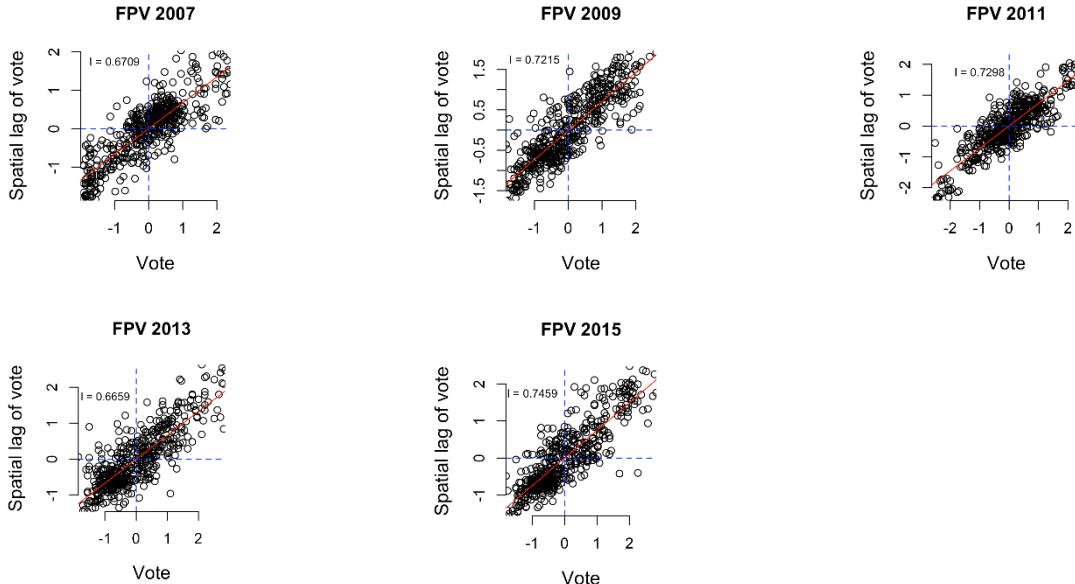

Panel B: Presidential vote

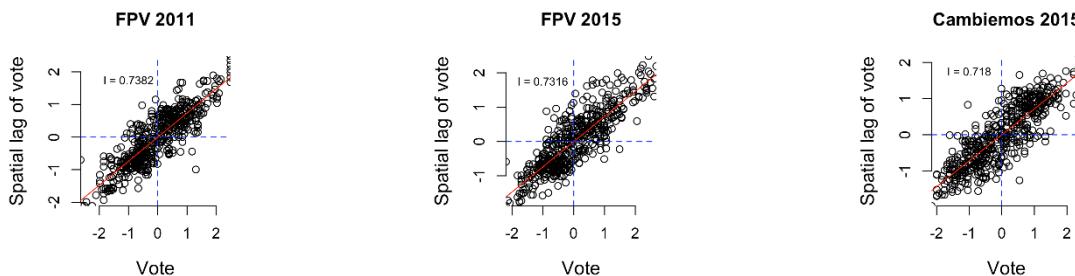

This figure displays the estimated permutation distribution of Moran's I for the vote shares of the FPV and Cambiemos for each election. Given the spatial weighting scheme, this test considers all possible ways of reassigning the values to the spatial locations. The null hypothesis is that the data (i.e., vote shares) were assigned to their spatial locations (i.e., departments) at random. The alternative hypothesis is that assignment to each particular location depended on the assignment of that location's neighbors. The histogram to the left shows the simulated I statistics for each of the 999 permutations. The blue vertical line indicates the actual value of the I statistic for the data as observed within the permutation distribution. The tests reject the null hypothesis of no spatial autocorrelation in the data ($p < .001$).

Figure A4: Moran scatterplot (dependent variables)

Panel A: Legislative vote

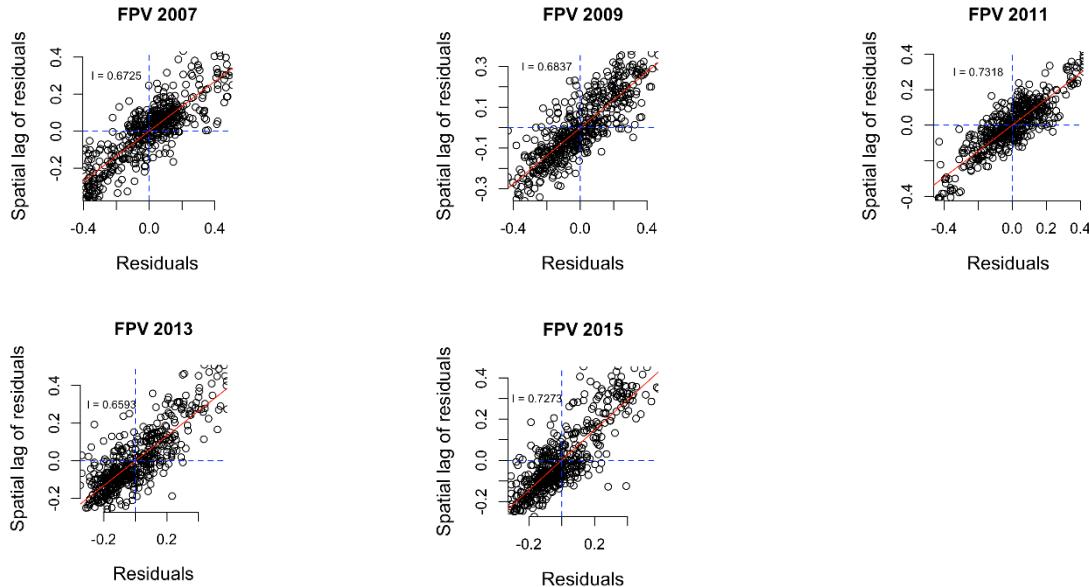

Panel B: Presidential vote

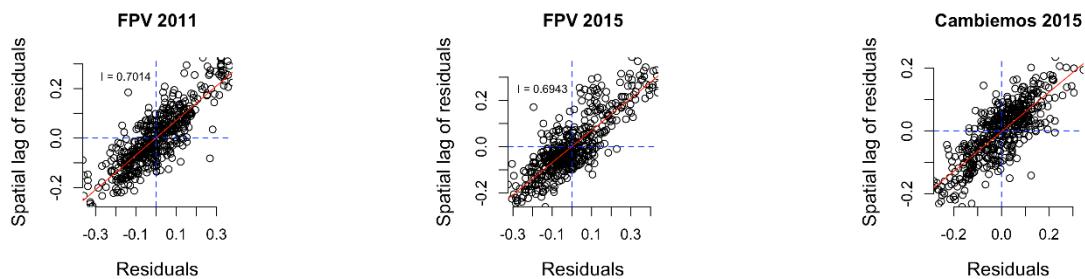

This figure shows Moran scatterplots between (a) the standardized values (z-scores) of vote shares for the FPV and Cambiemos in each election and (b) the standardized values of the spatially weighted, neighboring vote shares around the spatial unit (i.e. department) of interest. Positive slopes indicate positive spatial autocorrelation of the dependent variable. Spatial clustering of observations in the bottom-left and top-right corners of each plot indicate low-low and high-high autocorrelation.

Figure A5: Moran scatterplot (residuals)

Panel A: Legislative vote

Panel B: Presidential vote

This figure shows Moran scatterplots between (a) the residuals of vote shares regressed on soybean harvests for the FPV and Cambiemos in each election and (b) the spatially weighted, neighboring residuals around the spatial unit (i.e. department) of interest. Positive slopes indicate positive spatial autocorrelation of the residuals. Spatial clustering of observations in the bottom-left and top-right corners of each plot indicate low-low and high-high autocorrelation.

Table A1: Descriptive statistics (departmental level)

Variable	N	Mean	St. Dev.	Min	Max
FPV legislative vote 2005	499	0.423	0.184	0.000	0.930

C. Sensitivity Analysis

C1. Spatial lag

A spatial lag model incorporates spatial effects by including a spatially lagged dependent variable as a predictor. As in the manuscript's empirics, we estimate the following equation:

$$y_i = \alpha + y_i \mathbf{W}_i \rho + Harvest_i \beta + Lockouts_i \gamma + \mathbf{X}_i \delta + \varepsilon_i,$$

where y_i is the vote share for the FPV or Cambiemos in a given department i ; $Harvest_i$ is the log of the number of soybean harvested hectares; $Lockouts_i$ is the logged number of departmental lockouts occurring in 2008; \mathbf{X}_i denotes a matrix of agricultural-related variables (capital intensity and smallholding farms) and controls, which includes lagged vote shares and sociodemographic covariates; and ε_i is the error term.

In this specification, $y_i \mathbf{W}_i$ is the vector of the dependent variable y_i weighted by \mathbf{W}_i , which is a matrix of spatial weights specifying the degree of interdependence among observations.

C2. Random intercepts

Political and economic factors at the provincial level could also be driving voters' decisions to either support or punish national incumbents in Argentina. Variations in patterns of electoral support at particular levels of departmental soybean wealth could be the result of differences between provinces. We fit hierarchical regressions in which departments are nested into provinces. We estimate varying-intercept models that allow intercepts to vary by province in order to capture group-level differences.

We also include two variables that allow us to explore the influence of the provincial context on local electoral behavior: (i) whether the governor is not a member or an ally of the FPV;¹ and (ii) the fiscal balance of the provincial treasury.² Voters supporting governors who oppose the president in office might as well vote against the national government (see Calvo and Escobar 2005). Moreover, as the scholarship on fiscal federalism suggests (e.g. Wibbels 2005), voters judge national incumbents for the province's fiscal situation. In fiscally centralized polities such as Argentina, worsening balances may encourage citizens to cast a vote against the president in office.

We estimate the following equation:

$$y_{ij} = \alpha_j + Harvest_{ij}\beta + Lockouts_i\gamma + \mathbf{X}_{ij}\delta + Fiscal_j + Align_j + \varepsilon_{ij},$$

where α_j is the random intercept for a department i in province j ; $Fiscal_j$ is the annual percent change in a province's fiscal balance; and $Align_j$ is a dummy variable indicating whether the governor is aligned with the president. Moreover, α_{ij} is modeled as:

$$\alpha_{ij} = \alpha + Fiscal_j + Align_j + \eta_j,$$

with η_j being the error term for province j .

¹ Governor-president alignments were obtained at the Argentine political alignments data base by Cherny et al. (2015).

² Data come from the National Directorate of Provincial Fiscal Coordination (DNCFP), <http://www2.mecon.gov.ar/hacienda/dncfp/provincial.html>. A more common measure of economic performance would be provincial GDP per capita. However, most Argentine provinces failed to collect and report data on income and economic output systematically through the studied period. Refer to "Poco acceso a los datos de PBG por Provincia," *Chequeado*, January 22, 2015 (accessed December 13, 2017).

C3. Spatial fixed effects

We fit a regression model with spatial fixed effects—at the group level, or province—and Huber-White robust standard errors to correct for heteroscedasticity. We estimate the following equation:

$$y_i = \alpha + Harvest_i\beta + Lockouts_i\gamma + \mathbf{X}_i\delta + \theta_j + \varepsilon_i,$$

where θ_j are spatial dummies for each province j .

D. Criteria for Classifying Appointees

We classified all high-rank appointments to the ministries of Agriculture and Agroindustry between 2009 and 2017 as follows. We first gathered all the names included in the executive orders in which the president appoints an official—also dubbed “designaciones”—to know who they are. Next, using these names, we conducted several searches on multiple online sources (e.g., media outlets, personal webpages, social networking services for employment) to identify their career backgrounds and classify them according to one of the six categories outlined in the table below.

When an appointee meets the criteria for more than one category, we make our classification decision based on the following criteria. First, we always prioritize whether the appointee comes from a rural organization, regardless of his/her other past experience. If s/he held an important position in an organization representing agricultural interests, we automatically code him/her as “Agricultural organizations.” Second, if more than one category other than “Agricultural organizations” applies, we prioritize the seniority of prior positions—that is, we classify the appointee in accordance with the activity in which s/he has worked for the longest period of time. For instance, an appointee who was a chief scientist in a government biotechnological institute *and* a CEO in an important food company could be classified as “Government technical (agriculture)” or “Business and private sector” at the same time. However, if s/he spent more years working as the former than as the latter, then that appointee will be classified as “Government technical (agriculture).”

Table D.1: Categories for appointees in the ministries of Agriculture and Agroindustry

Agricultural organizations	The appointee has held a top position—e.g., president, vice-president, secretary, treasurer, board member—at one of the four main organizations representing the agricultural sector (SRA, CRA, FAA, and CONINAGRO) or an association specializing in agricultural technology (AACREA). For example, Ricardo Etchevehere, president of the SRA, appointed as Minister of Agroindustry on November 22, 2017 (Executive Order 947/2017).
Business and private sector	The appointee has held a top position—e.g., CEO, CFO, manager—in a private firm or association representing the industrial, service, or financial sector. For example, Santiago Moreno Hueyo, corporate manager of Pluspetrol, appointed as Undersecretary of Communications on December 13, 2017 (Executive Order 1031/2017).
Political career (unrelated)	The appointee has held a political position as an elected or unelected official requiring no technical or policy expertise. S/he could also be an outsider with no experience in government whatsoever. One example is Raúl A. Mircovich, former mayor of General Madariaga, Buenos Aires, appointed as Undersecretary of Institutional Coordination on February 17, 2012 (Executive Order 232/2012). A second example is Julián F. Mandriotti, songwriter, appointed as Secretary of Institutional Communications on February 17, 2012 (Executive Order 233/2012).
Government technical (agriculture)	The appointee has held a government position requiring technical or policy knowledge related to agricultural activity. These are mostly government institutes that conduct research in agricultural technology, such as the National Institute of Agricultural Research (INTA) or the National Food Safety and Quality Service (SENASA). For example, Carlos D. Casamiquela, Director of the Patagonia Regional Center at INTA, appointed as Minister of Agriculture on October 13, 2009 (Executive Order 1462/2009).
Government technical (non-agriculture)	The appointee has held a government position requiring technical or policy knowledge but unrelated to agricultural activity. For example, Juan M. Pomar, coordinator of a program to improve access to drinking water in the Province of Corrientes, appointed as Undersecretary of Family Farming on June 8, 2017 (Executive Order 400/2017).
Technocratic	The appointee is an expert professional with no linkages to government, such as an engineer, lawyer, university professor, or external consultant working for an NGO/non-profit organization or independently. For example, Lorenzo R. Basso, Agronomist, Dean of the School of Agronomy at the University of Buenos Aires and external consultant for multiple R&D projects, appointed as Secretary of Agriculture on October 2, 2009 (Executive Order 1369/2009).
N/A	No background information about the appointee was found.
